

# Import Modules and Standard Libraries

- To import a module into a script either import the entire module or just specific functions.

Example:

`import moduleName` - > this will import the entire module

`import moduleName as newName` - > imports module and renames it for use locally

`from module import function1, function2` --> imports specific functions ONLY from the module

`from module import *` --> imports everything from the module

- Python fetches the modules to import from the env variable path: `sys.path`
